

Binary Trees and Huffman Encoding

Binary Search Trees

Computer Science E-22
Harvard Extension School

David G. Sullivan, Ph.D.

Motivation: Maintaining a Sorted Collection of Data

- A *data dictionary* is a sorted collection of data with the following key operations:
 - *search* for an item (and possibly delete it)
 - *insert* a new item
- If we use a list to implement a data dictionary, efficiency = $O(n)$.

<i>data structure</i>	<i>searching for an item</i>	<i>inserting an item</i>
a list implemented using an array		
a list implemented using a linked list		

- In the next few lectures, we'll look at data structures (trees and hash tables) that can be used for a more efficient data dictionary.
- We'll also look at other applications of trees.

What Is a Tree?

- A tree consists of:
 - a set of *nodes*
 - a set of *edges*, each of which connects a pair of nodes
- Each node may have one or more *data items*.
 - each data item consists of one or more fields
 - *key field* = the field used when searching for a data item
 - multiple data items with the same key are referred to as *duplicates*
- The node at the “top” of the tree is called the *root* of the tree.

Relationships Between Nodes

- If a node N is connected to other nodes that are directly below it in the tree, N is referred to as their *parent* and they are referred to as its *children*.
 - example: node 5 is the parent of nodes 10, 11, and 12
- Each node is the child of *at most one* parent.
- Other family-related terms are also used:
 - nodes with the same parent are *siblings*
 - a node's *ancestors* are its parent, its parent's parent, etc.
 - example: node 9's ancestors are 3 and 1
 - a node's *descendants* are its children, their children, etc.
 - example: node 1's descendants are *all* of the other nodes

Types of Nodes

- A *leaf node* is a node without children.
- An *interior node* is a node with one or more children.

A Tree is a Recursive Data Structure

- Each node in the tree is the root of a smaller tree!
 - refer to such trees as *subtrees* to distinguish them from the tree as a whole
 - example: node 2 is the root of the subtree circled above
 - example: node 6 is the root of a subtree with only one node
- We'll see that tree algorithms often lend themselves to recursive implementations.

Path, Depth, Level, and Height

- There is exactly one *path* (one sequence of edges) connecting each node to the root.
- *depth* of a node = # of edges on the path from it to the root
- Nodes with the same depth form a *level* of the tree.
- The *height* of a tree is the maximum depth of its nodes.
 - example: the tree above has a height of 2

Binary Trees

- In a *binary tree*, nodes have *at most two* children.
- Recursive definition: a binary tree is either:
 - 1) empty, or
 - 2) a node (the root of the tree) that has
 - one or more data fields
 - a *left child*, which is itself the root of a binary tree
 - a *right child*, which is itself the root of a binary tree
- Example:

- How are the edges of the tree represented?

Representing a Binary Tree Using Linked Nodes

```
public class LinkedTree {
    private class Node {
        private int key;
        private LList data; // list of data for that key
        private Node left; // reference to left child
        private Node right; // reference to right child
        ...
    }
    private Node root;
    ...
}
```

Traversing a Binary Tree

- Traversing a tree involves *visiting* all of the nodes in the tree.
 - visiting a node = processing its data in some way
 - example: print the key
- We will look at four types of traversals. Each of them visits the nodes in a different order.
- To understand traversals, it helps to remember the recursive definition of a binary tree, in which every node is the root of a subtree.

Preorder Traversal

- preorder traversal of the tree whose root is N:
 - 1) visit the root, N
 - 2) recursively perform a preorder traversal of N's left subtree
 - 3) recursively perform a preorder traversal of N's right subtree

- Preorder traversal of the tree above:
7 5 2 4 6 9 8
- Which state-space search strategy visits nodes in this order?

Implementing Preorder Traversal

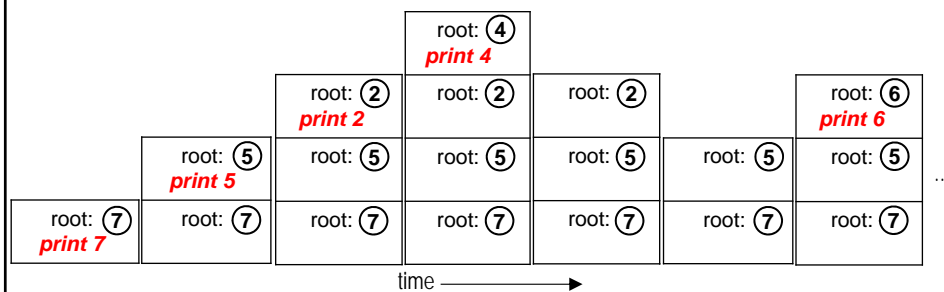

```
public class LinkedTree {  
    ...  
    private Node root;  
    public void preorderPrint() {  
        if (root != null)  
            preorderPrintTree(root);  
    }  
    private static void preorderPrintTree(Node root) {  
        System.out.print(root.key + " ");  
        if (root.left != null)  
            preorderPrintTree(root.left);  
        if (root.right != null)  
            preorderPrintTree(root.right);  
    }  
}
```

*Not always the
same as the root
of the entire tree.*

- `preorderPrintTree()` is a static, recursive method that takes as a parameter the root of the tree/subtree that you want to print.
- `preorderPrint()` is a non-static method that makes the initial call. It passes in the root of the entire tree as the parameter.

Tracing Preorder Traversal

```
void preorderPrintTree(Node root) {
    System.out.print(root.key + " ");
    if (root.left != null)
        preorderPrintTree(root.left);
    if (root.right != null)
        preorderPrintTree(root.right);
}
```

Postorder Traversal

- postorder traversal of the tree whose root is N:
 - 1) recursively perform a postorder traversal of N's left subtree
 - 2) recursively perform a postorder traversal of N's right subtree
 - 3) visit the root, N

- Postorder traversal of the tree above:
4 2 6 5 8 9 7

Implementing Postorder Traversal

```
public class LinkedTree {
    ...
    private Node root;

    public void postorderPrint() {
        if (root != null)
            postorderPrintTree(root);
    }

    private static void postorderPrintTree(Node root) {
        if (root.left != null)
            postorderPrintTree(root.left);
        if (root.right != null)
            postorderPrintTree(root.right);
        System.out.print(root.key + " ");
    }
}
```

- Note that the root is printed *after* the two recursive calls.

Tracing Postorder Traversal

```
void postorderPrintTree(Node root) {
    if (root.left != null)
        postorderPrintTree(root.left);
    if (root.right != null)
        postorderPrintTree(root.right);
    System.out.print(root.key + " ");
}
```

Inorder Traversal

- inorder traversal of the tree whose root is N:
 - 1) recursively perform an inorder traversal of N's left subtree
 - 2) visit the root, N
 - 3) recursively perform an inorder traversal of N's right subtree

- Inorder traversal of the tree above:
2 4 5 6 7 8 9

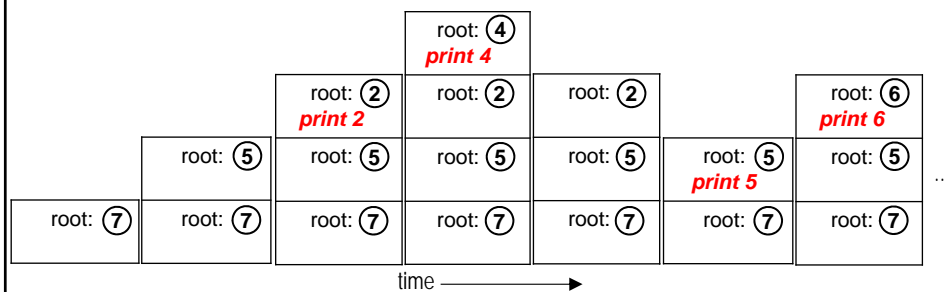

Implementing Inorder Traversal

```
public class LinkedTree {  
    ...  
    private Node root;  
    public void inorderPrint() {  
        if (root != null)  
            inorderPrintTree(root);  
    }  
    private static void inorderPrintTree(Node root) {  
        if (root.left != null)  
            inorderPrintTree(root.left);  
        System.out.print(root.key + " ");  
        if (root.right != null)  
            inorderPrintTree(root.right);  
    }  
}
```

- Note that the root is printed *between* the two recursive calls.

Tracing Inorder Traversal

```
void inorderPrintTree(Node root) {
    if (root.left != null)
        inorderPrintTree(root.left);
    System.out.print(root.key + " ");
    if (root.right != null)
        inorderPrintTree(root.right);
}
```

Level-Order Traversal

- Visit the nodes one level at a time, from top to bottom and left to right.

- Level-order traversal of the tree above: **7 5 9 2 6 8 4**
- Which state-space search strategy visits nodes in this order?
- How could we implement this type of traversal?

Tree-Traversal Summary

preorder: root, left subtree, right subtree

postorder: left subtree, right subtree, root

inorder: left subtree, root, right subtree

level-order: top to bottom, left to right

- Perform each type of traversal on the tree below:

Using a Binary Tree for an Algebraic Expression

- We'll restrict ourselves to fully parenthesized expressions and to the following binary operators: $+$, $-$, $*$, $/$
- Example expression: $((a + (b * c)) - (d / e))$
- Tree representation:

- Leaf nodes are variables or constants; interior nodes are operators.
- Because the operators are binary, either a node has two children or it has none.

Traversing an Algebraic-Expression Tree

- Inorder gives conventional algebraic notation.
 - print '(' before the recursive call on the left subtree
 - print ')' after the recursive call on the right subtree
 - for tree at right: $((a + (b * c)) - (d / e))$
- Preorder gives functional notation.
 - print '('s and ')'s as for inorder, and commas after the recursive call on the left subtree
 - for tree above: `subtr(add(a, mul t(b, c)), di vi de(d, e))`
- Postorder gives the order in which the computation must be carried out on a stack/RPN calculator.
 - for tree above: push a, push b, push c, mul ti ply, add, ...
- see ExprTree.java

Fixed-Length Character Encodings

- A character encoding maps each character to a number.
- Computers usually use fixed-length character encodings.
 - ASCII (American Standard Code for Information Interchange) uses 8 bits per character.

char	dec	binary
a	97	01100001
b	98	01100010
c	99	01100011
...

example: "bat" is stored in a text file as the following sequence of bits:
01100010 01100001 01110100

- Unicode uses 16 bits per character to accommodate foreign-language characters. (ASCII codes are a subset.)
- Fixed-length encodings are simple, because
 - all character encodings have the same length
 - a given character always has the same encoding

Variable-Length Character Encodings

- Problem: fixed-length encodings waste space.
- Solution: use a variable-length encoding.
 - use encodings of different lengths for different characters
 - assign shorter encodings to frequently occurring characters

- Example:

e	01
o	100
s	111
t	00

“test” would be encoded as

00 01 111 00 → 000111100

- Challenge: when decoding/decompressing an encoded document, how do we determine the boundaries between characters?
 - example: for the above encoding, how do we know whether the next character is 2 bits or 3 bits?
- One requirement: no character’s encoding can be the prefix of another character’s encoding (e.g., couldn’t have 00 and 001).

Huffman Encoding

- Huffman encoding is a type of variable-length encoding that is based on the actual character frequencies in a given document.
- Huffman encoding uses a binary tree:
 - to determine the encoding of each character
 - to decode an encoded file – i.e., to decompress a compressed file, putting it back into ASCII
- Example of a Huffman tree (for a text with only six chars):

Leaf nodes are characters.

Left branches are labeled with a 0, and right branches are labeled with a 1.

If you follow a path from root to leaf, you get the encoding of the character in the leaf

example: 101 = 'i'

Building a Huffman Tree

- 1) Begin by reading through the text to determine the frequencies.
- 2) Create a list of nodes that contain (character, frequency) pairs for each character that appears in the text.

- 3) Remove and “merge” the nodes with the two lowest frequencies, forming a new node that is their parent.

- left child = lowest frequency node
- right child = the other node
- frequency of parent = sum of the frequencies of its children
 - in this case, $11 + 23 = 34$

Building a Huffman Tree (cont.)

- 4) Add the parent to the list of nodes (maintaining sorted order):

- 5) Repeat steps 3 and 4 until there is only a single node in the list, which will be the root of the Huffman tree.

Completing the Huffman Tree Example I

- Merge the two remaining nodes with the lowest frequencies:

Completing the Huffman Tree Example II

- Merge the next two nodes:

Completing the Huffman Tree Example II

- Merge again:

Completing the Huffman Tree Example IV

- The next merge creates the final tree:

- Characters that appear more frequently end up higher in the tree, and thus their encodings are shorter.

The Shape of the Huffman Tree

- The tree on the last slide is fairly symmetric.
- This won't always be the case!
 - depends on the frequencies of the characters in the document being compressed
- For example, changing the frequency of 'o' from 11 to 21 would produce the tree shown below:

- This is the tree that we'll use in the remaining slides.

Using Huffman Encoding to Compress a File

- 1) Read through the input file and build its Huffman tree.
- 2) Write a file header for the output file.
 - include an array containing the frequencies so that the tree can be rebuilt when the file is decompressed.
- 3) Traverse the Huffman tree to create a table containing the encoding of each character:

a	?
e	?
i	101
o	100
s	111
t	00

- 4) Read through the input file a second time, and write the Huffman code for each character to the output file.

Using Huffman Decoding to Decompress a File

- 1) Read the frequency table from the header and rebuild the tree.
- 2) Read one bit at a time and traverse the tree, starting from the root:
 - when you read a bit of 1, go to the right child
 - when you read a bit of 0, go to the left child
 - when you reach a leaf node, record the character,
 - return to the root, and continue reading bits

The tree allows us to easily overcome the challenge of determining the character boundaries!

example: 101111110000111100

101 = right, left, right = i
 111 = right, right, right = s
 110 = right, right, left = a
 00 = left, left = t
 01 = left, right = e
 111 = right, right, right = s
 00 = left, left = t

Binary Search Trees

- Search-tree property: for each node k :
 - all nodes in k 's left subtree are $< k$
 - all nodes in k 's right subtree are $\geq k$
- Our earlier binary-tree example is a search tree:

Searching for an Item in a Binary Search Tree

- Algorithm for searching for an item with a key k :
 - if $k ==$ the root node's key, you're done
 - else if $k <$ the root node's key, search the left subtree
 - else search the right subtree
- Example: search for 7

Implementing Binary-Tree Search

```
public class LinkedTree {    // Nodes have keys that are ints
    ...
    private Node root;

    public List search(int key) {
        Node n = searchTree(root, key);
        if (n == null)
            return null;    // no such key
        else
            return n.data;    // return list of values for key
    }

    private static Node searchTree(Node root, int key) {
        // write together
    }
}
```

Inserting an Item in a Binary Search Tree

- We want to insert an item whose key is k .
- We traverse the tree as if we were searching for k .
- If we find a node with key k , we add the data item to the list of items for that node.
- If we don't find it, the last node we encounter will be the parent P of the new node.
 - if $k < P$'s key, make the new node P 's left child
 - else make the node P 's right child
- *Special case*: if the tree is empty, make the new node the root of the tree.
- The resulting tree is still a search tree.

example: insert 35

Implementing Binary-Tree Insertion

- We'll implement part of the `insert()` method together.
- We'll use iteration rather than recursion.
- Our method will use two references/pointers:
 - `trav`: performs the traversal down to the point of insertion
 - `parent`: stays one behind `trav`
 - like the `trail` reference that we sometimes use when traversing a linked list

Implementing Binary-Tree Insertion

```
public void insert(int key, Object data) {
    Node parent = null;
    Node trav = root;
    while (trav != null) {
        if (trav.key == key) {
            trav.data.addItem(data, 0);
            return;
        }
    }

    Node newNode = new Node(key, data);
    if (root == null) // the tree was empty
        root = newNode;
    else if (key < parent.key)
        parent.left = newNode;
    else
        parent.right = newNode;
}
```

Deleting Items from a Binary Search Tree

- Three cases for deleting a node x
- Case 1:** x has no children.
Remove x from the tree by setting its parent's reference to null.

- Case 2:** x has one child.
Take the parent's reference to x and make it refer to x 's child.

Deleting Items from a Binary Search Tree (cont.)

- **Case 3:** x has two children
 - we can't just delete x . why?
 - instead, we replace x with a node from elsewhere in the tree
 - to maintain the search-tree property, we must choose the replacement carefully
 - example: what nodes could replace 26 below?

Deleting Items from a Binary Search Tree (cont.)

- **Case 3:** x has two children (continued):
 - replace x with the smallest node in x 's right subtree—call it y
 - y will either be a leaf node or will have one right child. why?
- After copying y 's item into x , we delete y using case 1 or 2.

ex:
delete 26

Implementing Binary-Tree Deletion

```
public LList delete(int key) {
    // Find the node and its parent.
    Node parent = null;
    Node trav = root;
    while (trav != null && trav.key != key) {
        parent = trav;
        if (key < trav.key)
            trav = trav.left;
        else
            trav = trav.right;
    }

    // Delete the node (if any) and return the removed items.
    if (trav == null) // no such key
        return null;
    else {
        LList removedData = trav.data;
        deleteNode(trav, parent);
        return removedData;
    }
}
```

- This method uses a helper method to delete the node.

Implementing Case 3

```
private void deleteNode(Node toDelete, Node parent) {
    if (toDelete.left != null && toDelete.right != null) {
        // Find a replacement - and
        // the replacement's parent.
        Node replaceParent = toDelete;

        // Get the smallest item
        // in the right subtree.
        Node replace = toDelete.right;
        // What should go here?

        // Replace toDelete's key and data
        // with those of the replacement item.
        toDelete.key = replace.key;
        toDelete.data = replace.data;

        // Recursively delete the replacement
        // item's old node. It has at most one
        // child, so we don't have to
        // worry about infinite recursion.
        deleteNode(replace, replaceParent);
    } else {
        ...
    }
}
```

Implementing Cases 1 and 2

```
private void deleteNode(Node toDelete, Node parent) {  
    if (toDelete.left != null && toDelete.right != null) {  
        ...  
    } else {  
        Node toDeleteChild;  
        if (toDelete.left != null)  
            toDeleteChild = toDelete.left;  
        else  
            toDeleteChild = toDelete.right;  
        // Note: in case 1, toDeleteChild  
        // will have a value of null.  
  
        if (toDelete == root)  
            root = toDeleteChild;  
        else if (toDelete.key < parent.key)  
            parent.left = toDeleteChild;  
        else  
            parent.right = toDeleteChild;  
    }  
}
```

Efficiency of a Binary Search Tree

- The three key operations (search, insert, and delete) all have the same time complexity.
 - insert and delete both involve a search followed by a constant number of additional operations
- Time complexity of searching a binary search tree:
 - best case: $O(1)$
 - worst case: $O(h)$, where h is the height of the tree
 - average case: $O(h)$
- What is the height of a tree containing n items?
 - it depends! why?

Balanced Trees

- A tree is *balanced* if, for each node, the node's subtrees have the same height or have heights that differ by 1.
- For a balanced tree with n nodes:
 - height = $O(\log_2 n)$.
 - gives a worst-case time complexity that is logarithmic ($O(\log_2 n)$)
 - the best worst-case time complexity for a binary tree

What If the Tree Isn't Balanced?

- Extreme case: the tree is equivalent to a linked list
 - height = $n - 1$
 - worst-case time complexity = $O(n)$
- We'll look next at search-tree variants that take special measures to ensure balance.
